

No typed prices

Sellers pick a customer and a product. The price is computed, never keyed in.

Simulated first

Every change shows its peso impact per month before anyone approves it.

Nothing unlogged

12 kinds of events — publish, quote, print, import — recorded as they happen.

How a price travels

Below the floor, the quote stops: the seller must request approval, and the request cannot be submitted without a competitor reading attached.

Who can do what

Role	Sees	Can change	Cannot
Manager	Everything: boards, exceptions, log, config	Cost, margins, buffers, client premiums and discounts, users, client list	Publish alone — a second manager must verify
Seller	Own price lists, own customers, own past quotes	Nothing priced — only sends quotes and requests	Type a price, or send below floor
Messenger	Competitor price watch only	Adds competitor readings with a photo	See any MGC price, anywhere
Viewer	One assigned price list	Acknowledges receipt	Reach quotes, exceptions or the log

What it stops

- **Quotes below the floor** — blocked, and only released by a manager decision with a reason on record.
- **Selling on yesterday's cost** — if the cost basis moves and no one republishes, sending is frozen.
- **Screenshots of unknown vintage** — every printed list and quotation carries its version, date and reference.
- **Silent discounts** — each premium and discount is a named line, itemised per client.

Six checks and balances

- **No price typing** anywhere in the seller's screen.
- **Freshness gate** — a cost change freezes sending until republished.
- **Simulate before approve** — impact in pesos per month, accounts that fall below floor, and accounts that cross above the nearest competitor.
- **Four eyes** — the verifier can never be the drafter.
- **Immutable quotes** — a sent quotation keeps its price, with a hash, after any later change.
- **Versioned prices** — a price row is never edited; publishing closes the old one and inserts a new one.

The prototype runs today — 7 price lists, 12 products, 175 demo clients (50 bulk, 120 commercial), 8 users across 4 roles, 17 automated pricing tests passing. It is a working tool for the pricing cycle, not a mockup: quotes, approvals, publishing, notices and the audit trail all function. Every figure shown in the demo is an illustrative placeholder, not MGC's costs, margins or customers.

Ranked by control and cascade

Control = how tightly management can set and enforce the rule. **Cascade** = how fast and how far the result reaches the people who act on it. The features worth the most sit high on both.

Capability	Control	Cascade	What it buys you
MPL calculator, 5 stages	5	5	One approved publish moves every price list, quote screen and PDF at the same instant. Two names required.
Price lists + PL notices	3	5	A per-audience list plus a matrix of who has acknowledged version n, with date and time. Ends "I never got it".
Quote desk without a price field	5	4	Discounting becomes a request with a reason and a competitor reading, not a favour granted in the field.
Event log, 12 event types	4	3	Who changed what, when, why, and on whose instruction — written by the same action, never typed in after.
Configuration: users, channels, clients	5	3	Roles, price-list access, the channel list and its order, and the whole client list (CSV import/export) — maintained in-app, without IT.
Client pricing grid	4	3	Every client of a channel on one page: premiums, discounts and a live total per client, all routed into the proposal.
Competitor price watch	2	4	Weekly readings per brand and zone, photo required, 10% outlier challenge. Feeds every discount request.
Comparison boards, 5 at a time	3	2	Clients, products or channels side by side, showing proposed prices while a change is still being drafted.

For IT

What it is today

- Plain HTML and JavaScript modules. **No build step, no packages, no server code.** Runs from any static web host, a shared folder or a laptop.
- Prototype data lives in the browser (localStorage), with export/import and reset. Nothing leaves the machine.
- The pricing engine is one dependency-free file covered by 17 tests that run in the browser.
- Money is whole centavos end to end — no floating-point drift, two decimals everywhere.

Path to production

- The engine file moves unchanged into the server and the web client — the arithmetic is written once.
- Every write already passes through one function; that becomes the API call. The event object is already the audit table row.
- Seed collections map to tables; effective-dated rows map to a date-range column that makes overlapping prices impossible.
- **Needed for production:** real accounts and passwords, server-enforced roles, a database, backups. The role switcher is a stand-in for login.

Decisions we need from you

Decision	Why it matters	Status
The floor	Today the floor is cost + hauling + margin. On current data, 5 of 10 sample clients already sit below it because of long-standing discounts.	Open — needs a ruling
Who may instruct and verify	Approval records both names. We can restrict the lists to named people in Configuration.	Ready to set
Client master data	Clients, contracts, volumes and premiums come in by CSV. Someone must own that list.	Ready to load
Go-live scope	Pilot one channel for a month, or move all seven at the next price change.	Your call

The short version. Price setting becomes a five-stage, two-signature procedure that takes minutes. Price telling becomes one versioned list per audience, with proof of receipt. Everything in between — quotes, discounts, competitor prices, printed lists — is recorded as it happens, so a price can always be explained after the fact.
